

ABSTRACT

A system for aggregating and displaying Internet account information on a client processor. The client processor is programmed to display a view page from a host server. The view page has 1 to n columns. Each of the columns has at least one monitor. The user populates the monitors with links to selected web-sites. The system retrieves data from the selected web-sites and displays the retrieved data in the monitors. The system allows users to modify the arrangement of the monitors on the view page, create multiple view pages, add new monitors, and modify monitors. The system provides one click access to web-sites, including sites that require a login protocol. The system provides a fast login function, which enables users to setup and access frequently visited websites with a click of a mouse. The system can be accessed via mobile devices, such as cell phones.
